## *EZ Dock Installation Example – Spud Pipe Anchorage*

This type of anchorage uses a small diameter pipe, usually between two inches and four inches in diameter, to provide the horizontal support necessary to keep the docks in place. The use of spud pipes will allow the docks to move up and down with most water fluctuations with little maintenance. The spud pipes are normally driven or screwed into the bottom of the body of water a distance of three to eight feet (roughly 1/4 to 1/3 the total length of the pipe). This type of anchorage is typically used in most private and some light duty commercial installations. The size and number of spud pipes will be determined by the conditions encountered. Spud pipes are normally limited to water depths of fifteen feet and under.
